• **Passing Arguments to Threads**

- The *pthread_create*() function allows the programmer to pass one argument to the thread function.
- For cases where multiple arguments must be passed, this limitation is easily overcome by creating a **structure**.
- This structure contains all of the arguments, and then a pointer is passed to that structure in the *pthread* create() routine.
- All arguments must be passed by reference and cast to (void *).
- Threads have non-deterministic start-up and scheduling.
- • How can you safely pass data to newly created threads?

Thread Basics: Passing Arguments II

• **Example:** Demonstrates how to pass a simple integer to each thread.

```
long *taskids[NUM THREADS]:
for(t=0: t<NUM THREADS: t++)
   taskids[t] = (lona *) malloc(sizeof(long)):
   *taskids[t] = t:
   printf("Creating thread %ld\n", t);
   rc = phread create(\&threads[t], NULL, Printhello, (void *) taskids[t]);\cdots
```
Figure: Passing single argument to thread function.

Thread Basics: Passing Arguments III

• **Example:** Demonstrates how to pass/setup multiple arguments to thread function via a structure.

```
struct thread data{
   int thread id:
  int sum;
  char *message;
\};
struct thread_data thread_data_array[NUM_THREADS];
void *PrintHello(void *threadarg)
  struct thread data *my data;
   my data = (struct thread data *) threadarg;
   taskid = my data - xthread id;sum = my data->sum;hello_msg = my_data->message;
   . . .
int main (int argc, char *argv[])
   thread_data_array[t].thread_id = t;
   thread data array[t].sum = sum;
   thread data_array[t].message = messages[t];
   rc = pthread_create(&threads[t], NULL, PrintHello,
        (void *) &thread_data_array[t]);
```

Thread Basics: Cancellation I

• **Cancellation.**

- Consider a simple program to evaluate a set of positions in a chess game.
- Assume that there are k moves, each being evaluated by an independent thread.
- If at any point of time, a position is established to be of a certain quality, the other positions that are known to be of worse quality must stop being evaluated.
- In other words, the threads evaluating the corresponding board positions must be canceled.
- Posix threads provide this cancellation feature.
- • A thread may cancel itself or cancel other threads.

Synchronization [Primitives in Pthreads](#page-11-0)

Thread Basics: Cancellation II

• **pthread_cancel**.

- 1 int
- 2 pthread_cancel (
- pthread t thread);
- Here, thread is the handle to the thread to be canceled. When a call to this function is made, a cancellation is sent to the specified thread.
- It is not guaranteed that the specified thread will receive or act on the cancellation. Threads can protect themselves against cancellation.
- When a cancellation is actually performed, cleanup functions are invoked for reclaiming the thread data structures.
- The **pthread cancel** function returns after a cancellation has been sent. The cancellation may itself be performed later.

Synchronization [Primitives in Pthreads](#page-11-0)

Thread Basics: Joining and Detaching I

- **Joining and Detaching Threads.**
- The main program must wait for the threads to run to completion.
- "Joining" is one way to accomplish synchronization between threads.
- Function **pthread_join** which suspends execution of the calling thread until the specified thread terminates.

```
1
    imt\overline{2}pthread join (
3
          pthread t thread,
4
          void * *ptr);
```
• A call to this function waits for the termination of the thread whose id is given by thread.

Synchronization [Primitives in Pthreads](#page-11-0)

Thread Basics: Joining and Detaching II

• A call to this function waits for the termination of the thread whose id is given by thread.

Figure: Threads joining.

- On a successful call to **pthread_join**, the value passed to **pthread exit** is returned in the location pointed to by ptr.
- On successful completion, **pthread_join** returns 0, else it returns an error-code.

Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization [Primitives in Pthreads](#page-11-0)

Thread Basics: Joining and Detaching III

- When a thread is created, one of its attributes defines whether it is **joinable or detached**.
- Only threads that are created as joinable can be joined. If a thread is created as detached, it can never be joined.
- The final draft of the POSIX standard specifies that threads should be created as joinable.
- To explicitly create a thread as joinable or detached, the **attr** argument in the *pthread create*() routine is used.
- **Detaching**:
- The **pthread detach()** routine can be used to explicitly detach a thread even though it was created as joinable.
- If a thread requires joining, consider explicitly creating it as joinable (portability).
- If you know in advance that a thread will never need to join with another thread, consider creating it in a detached state (resources).

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization [Primitives in Pthreads](#page-11-0)

- **Reentrant function**s are those that can be safely called when another instance has been suspended in the middle of its invocation.
- All thread functions must be reentrant because a thread can be preempted in the middle of its execution.
- If another thread starts executing the same function at this point, a non-reentrant function might not work as desired.

Synchronization Primitives: Mutex I

- While communication is implicit in shared-address-space programming,
- much of the effort associated with writing correct threaded programs is spent on **synchronizing concurrent threads** with respect to their data accesses or scheduling.
- Using **pthread_create** and **pthread_join** calls, we can create concurrent tasks.
- These tasks work together to manipulate data and accomplish a given task.
- When multiple threads attempt to manipulate the same data item,
- • the results can often be **incoherent** if proper care is not taken to synchronize them.

Dr. Cem Özdogan ˘

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization [Primitives in Pthreads](#page-11-0)

Synchronization Primitives: Mutex II

• Consider the following code fragment being executed by multiple threads.

```
\mathbf{1}/* each thread tries to update variable best cost
                                               as follows */
\overline{2}3
    if (my cost < best cost)
4
         best cost = mv cost;
```
- The variable my_cost is thread-local and best_cost is a global variable shared by all threads.
- This is an undesirable situation, sometimes also referred to as a **race condition**.
- So called because the result of the computation depends on the race between competing threads.

[Programming Shared](#page-0-0) Memory II

Dr. Cem Özdogan ˘

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization Primitives: Mutex III

- To understand the problem with shared data access, let us examine one execution instance of the above code fragment.
- Assume that there are two threads,
- The initial value of best cost is 100.
- The values of my cost are 50 and 75 at threads t1 and t2, respectively.
- If both threads execute the condition inside the if statement concurrently, then both threads enter the then part of the statement.
- Depending on which thread executes first, the value of best cost at the end could be either 50 or 75.
- There are two problems here:
	- 1 non-deterministic nature of the result;
	- 2 more importantly, the value 75 of best cost is inconsistent in the sense that no serialization of the two threads can possibly yield this result.

[Programming Shared](#page-0-0) Memory II

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization Primitives: Mutex IV

- Race condition occurred because the test-and-update operation is an **atomic operation**;
	- i.e., the operation should not be broken into sub-operations.
- Furthermore, the code corresponds to a **critical segment**;
	- i.e., a segment that must be executed by only one thread at any time.
- Many statements that seem atomic in higher level languages such as C may in fact be non-atomic.
	- i.e., a statement of the form global_count $+= 5$ may comprise several assembler instructions and therefore must be handled carefully.
- Threaded APIs provide support for implementing critical sections and atomic operations using **mutex**-locks (mutual exclusion locks).

[Programming Shared](#page-0-0) Memory II

Dr. Cem Özdogan ˘

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization Primitives: Mutex V

- Mutex-locks have two states: locked and unlocked.
- At any point of time, **only one thread can lock a mutex lock**.
- A lock is an atomic operation.
	- To access the shared data, a thread must first try to acquire a mutex-lock.
	- If the mutex-lock is already locked, the process trying to acquire the lock is **blocked**.
	- This is because a locked mutex-lock implies that there is another thread currently in the critical section and that no other thread must be allowed in.
	- When a thread leaves a critical section, it must unlock the mutex-lock so that other threads can enter the critical section.
- All mutex-locks must be initialized to the unlocked state at the beginning of the program.

Synchronization [Primitives in Pthreads](#page-11-0) [Mutual Exclusion for Shared](#page-11-0)

Variables

Synchronization Primitives: Mutex VI

• The function **pthread_mutex_lock**;

```
1.
     i<sub>m</sub>+
\overline{2}pthread mutex lock (
3
           pthread mutex_t *mutex_lock);
```
- A call to this function attempts a lock on the mutex-lock mutex lock.
- The data type of a *mutex lock* is predefined to be pthread mutex t.
- If the mutex-lock is already locked, the calling thread blocks; otherwise the mutex-lock is locked and the calling thread returns.
- A successful return from the function returns a value 0. Other values indicate error conditions such as deadlocks.

Dr. Cem Özdogan ˘

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization Primitives: Mutex VII

• The function **pthread_mutex_unlock**;

```
1
     i<sub>nt</sub>\overline{2}pthread_mutex_unlock (
3
           pthread mutex t *mutex lock);
```
- On leaving a critical section, a thread must **unlock the mutex-lock** associated with the section.
- If it does not do so, no other thread will be able to enter this section, typically resulting in a deadlock.
- On calling **pthread mutex unlock** function, the lock is relinquished and one of the blocked threads is **scheduled** to enter the critical section.

[Programming Shared](#page-0-0) Memory II

Dr. Cem Özdogan ˘

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

Variables

[Joining and Detaching](#page-7-0) **Threads**

Synchronization Primitives: Mutex VIII

- The specific thread is determined by the **scheduling policy**.
- if the thread priority scheduling is not implied, the assignment will be left to the native system scheduler and may appear to be more or less **random**.
- **Mutex variables** must be declared with type pthread mutex t , and must be initialized before they can be used.
- There are two ways to initialize a mutex variable:
	- 1 Statically, when it is declared. For example: $pthread_mutex_t mymutex =$ PTHREAD_MUTEX_INITIALIZER:
	- 2 Dynamically, with the **pthread_mutex_init()** routine. This method permits setting mutex object attributes, attr.
- If a programmer attempts a **pthread_mutex_unlock** on a previously unlocked mutex or one that is locked by another thread, the effect is undefined.

[Programming Shared](#page-0-0) Memory II

Dr. Cem Özdogan ˘

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization Primitives: Mutex IX

• The function **pthread** mutex init;

```
1
     i<sub>nt</sub>\overline{2}pthread mutex init (
3
          pthread mutex t *mutex lock,
4
          const pthread mutexattr t *lock attr);
```
- We need one more function before we can start using mutex-locks, namely, a function to initialize a mutex-lock to its unlocked state.
- The mutex is initially unlocked.
- The attributes of the mutex-lock are specified by lock attr.
- If this argument is set to NULL, the default mutex-lock attributes are used (normal mutex-lock).

[Programming Shared](#page-0-0) Memory II

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization Primitives: Overheads of Locking I

- Locks represent serialization points since critical sections must be executed by threads one after the other.
- Encapsulating large segments of the program within locks can, therefore, lead to **significant performance degradation**.
- It is therefore important to minimize the size of critical sections and to handle critical sections and shared data structures with extreme care.
- It is often possible to reduce the idling overhead associated with locks using an alternate function, pthread_mutex_trylock.
- It does not have to deal with queues associated with locks for multiple threads waiting on the lock.

Dr. Cem Özdogan ˘

Thread Basics: [Passing Arguments,](#page-2-0) Cancellation and Joining

[Passing Arguments to](#page-2-0) Threads

[Thread Cancellation](#page-5-0)

[Joining and Detaching](#page-7-0) **Threads**

Synchronization [Primitives in Pthreads](#page-11-0)

Synchronization Primitives: Overheads of Locking II

• The function **pthread_mutex_trylock**;

```
1
    i<sub>nt</sub>2
   pthread mutex trylock
R
         pthread mutex t *mutex lock);
```
- This function attempts a lock on *mutex lock*.
	- If the lock is successful, the function returns a zero.
	- If it is already locked by another thread, **instead of blocking** the thread execution, it returns a value EBUSY.
	- This allows the thread to **do other work** and to poll the mutex for a lock.
- • Furthermore, **pthread_mutex_trylock** is typically much faster than **pthread_mutex_lock** on typical systems.
